Mitsubishi Electric’s contributions to energy conservation for reducing greenhouse gas emissions include the development of MDU breakers as energy-saving devices. The MDU breaker has a current transformer (CT) and a voltage transformer (VT) in the circuit breaker main body for measuring the load current, line voltage, electric power, electric energy, and other electric variables. The main features are listed below.

(1) Space-saving and easy to install
(2) High performance and multifunction

Recent years have seen an increased demand for more advanced energy management activities, such as the leveling of electric power load. Mitsubishi Electric has developed new models of the W&WS series that deliver higher performance. For enhanced usability, these models were designed with an emphasis on the following two aspects:

(1) Improvement of visibility
(2) Expansion of display functions

This paper describes the main features of the new models of the W&WS series along with several technical issues and their countermeasures.

1. Product models and features of the latest series

1.1 Product models

Table 1 shows the lineup. The newly added models (enclosed with the black lines in Table 1) can display their specification data in the panel openings (breaker mounting).
mounting), in addition to the 250A frame LCD type. The external mounting type is made selectable when required, as with the 6-digit 7-segment LED display type.

1.2 Features of the latest MDU series
For enhanced usability, the visibility of the latest MDU breaker series was improved and the display functions were expanded.

1.2.1 Improvement of visibility
The latest models have LCDs with high-luminance white backlighting. Normal display (Fig. 1(a)) or color inversion (Fig. 1(b)) is selectable depending on the use environment.

1.2.2 Expansion of display functions
The display functions listed below were installed using the LCD function.

1. Setting item list display function (only for external mounting)
This display function shows the setting items for the overcurrent tripping characteristics (to be set using the breaker main body) and others on the display (Fig. 2).

2. Free item display function (only for external mounting)
The free item display function enables the registration of all necessary measurement items to be displayed (Fig. 3).

3. Three-phase (four-phase) display function
A display function for each phase of the measurement items (current and voltage) is provided (Fig. 4). In addition, the screen orientation can be changed as a specification when a breaker is installed in the horizontal direction.

4. Function for displaying red backlight when an alarm is issued
The backlight color when an alarm is issued has been changed to red to make it easier to notice an error from a distance (Fig. 5). In addition, the display format for the red backlight (lighting up or blinking) can be selected as a specification.

2. Technical issues and their countermeasures
2.1 Improvement of the design efficiency of LCD backlight
To improve the visibility of the LCDs, a backlight with light guide plates was adopted. Two types of backlight — white and red — are used. Simulation was carried out to reduce the trial and error process, which made it possible to efficiently design a backlight with high and even luminance. Specifically, the incident end face and surface shape of the light guide plate, the mounted location and required number of backlight LEDs, the shape of the reflection and diffusion sheets, and other conditions were changed to identify those that produced a high and even luminance over the entire LCD.

Figure 6 shows the simulation results. Figure 7 shows a circuit board with backlight LEDs mounted and a light guide plate.
2.2 Front loading for countermeasures against EMI

Electrical noise emitted from electrical equipment propagates through space or wireways and may affect the operation of other electrical equipment and radio equipment, so the emission levels need to be equal to or lower than the standard values. For products with many restrictions on the mounting area, in particular, a revision (e.g., addition or change of parts and change of circuit board patterns) in the evaluation phase, which is a later stage of development, requires redesigning under many restrictions along with reevaluation due to the revision, greatly affecting the development schedule. This section describes front loading performed in the circuit design and circuit board design phases (early stages of the development) for countermeasures against conducted and radiated noise.

2.2.1 Front loading for countermeasures against conducted noise

(1) Consideration of circuit analysis models

The noise level must be reduced to that equal to or lower than the standard value by a noise filter circuit (CR passive filter) in the power circuit input stage installed as a countermeasure against conducted noise. Since there are many restrictions on mounting, a revision to the circuit due to the addition of a filter stage and other reasons requires heavy reworking, which may delay the delivery date. Therefore, we focused on the fact that the switching transformer of the power circuit is the propagation path of normal noise and common noise that are the cause of conducted noise: a simulation was performed using a circuit analysis model with a high-accuracy equivalent circuit of the switching transformer to evaluate the circuit. Figure 8 illustrates the equivalent circuit of the switching transformer.

For the equivalent circuit constants of the switching transformer (e.g., leakage inductance and winding stray capacitance), the values were calculated by measuring the impedance of the parts adopted.

(2) Simulation results and measured data

The high-accuracy equivalent circuit analysis model was used for simulation in the early design stage to determine the number of filter stages and the constants of the parts such that the noise level would be reduced to the standard value or lower, where the carrier frequency (fc) of the switched mode power supply was 75 kHz (design value). Next, prototypes were fabricated based on these circuit conditions and they were used to measure the noise level. The evaluation results were excellent. In other words, front loading in which high-accuracy simulation is performed in the early design stage to check the necessary filter configuration, reduced the development period. Figure 9(a) shows the simulation results of the conducted noise. Figure 9(b) shows the measurement results using an actual product.

2.2.2 Front loading for countermeasures against radiated noise

As countermeasures against radiated noise,
resonance between a power supply and ground plane that could generate radiated noise was analyzed in the circuit board design phase to optimize the shape from the power supply to the ground plane. In addition, it was determined to add bypass capacitors. This achieved the design to suppress the peak at a specific frequency and reduce the noise voltage level to the standard value or lower. Figure 10 shows the analysis results of the resonance of circuit boards before and after the countermeasures against radiated noise.

3. Conclusion
This paper described the features of the latest MDU breaker models along with several technical issues and their countermeasures. We will continue developing high-quality products that meet user needs.
